

**pH Scale**

- The pH scale is used to express concentration of  $\text{H}_3\text{O}^+$  in an aqueous solution.
- For expressing the  $\text{H}_3\text{O}^+$  ion concentration a logarithmic scale was devised by P.L.Sorensen.
- The pH of a solution is defined as the negative logarithm (log) of the hydronium ion (hydrogen ion) concentration.
- $\text{pH} = -\log [\text{H}_3\text{O}^+]$
- $[\text{H}_3\text{O}^+] = 1 \times 10^{-\text{pH}}$
- In similar way, pOH is the negative logarithm of the hydroxide ion concentration.  
 $\text{pOH} = -\log [\text{OH}^-]$
- In pure water,
  - $K_w = [\text{H}_3\text{O}^+] [\text{OH}^-] = 1 \times 10^{-14} \text{ M}^2$
  - $[\text{H}_3\text{O}^+] = [\text{OH}^-] = 1 \times 10^{-7} \text{ M}$
  - $\text{pH} = \text{pOH} = -\log (1 \times 10^{-7})$
  - $\text{pH} = \text{pOH} = 7$
  - Therefore  $\text{pH} + \text{pOH} = \text{p}K_w = 14$
- Concept is:
  - At 25 °C,
  - Acidic solution :  $\text{pH} < 7.0$  ;  $\text{pOH} > 7.0$
  - Basic solution :  $\text{pH} > 7.0$  ;  $\text{pOH} < 7.0$
  - Neutral solution :  $\text{pH} = 7.0$  ;  $\text{pOH} = 7.0$

**Buffer Solution**

- A solution that maintains its pH when a small amount of a strong acid or a strong base is added to it. It is also defined as a solution which contains weak acid or weak base with salt that has its conjugate pair.
- Two types of buffer solution:
  - Acidic buffer solution
  - Basic buffer solution
- **ACIDIC BUFFER SOLUTION:** Has  $\text{pH} < 7$ : An acidic buffer solution is made up of a weak acid and its salt (containing its conjugate base)
- Example:  $\text{CH}_3\text{COOH} / \text{CH}_3\text{COONa}$ ,  $\text{H}_2\text{CO}_3 / \text{NaHCO}_3$ ,  $\text{H}_3\text{PO}_4 / \text{NaH}_2\text{PO}_4$ ,  $\text{HCOOH} / \text{HCOONa}$
- equation, popularly known as the Henderson equation
- $\text{pH of acidic buffer} = \text{p}K_a + \log ([\text{salt}]/[\text{acid}])$
- **Basic Buffer Solution:** Has  $\text{pH} > 7$ : Basic buffer solution is made up of a weak base and its salt (containing its conjugate)
- The equation  $\text{pOH of basic buffer} = \text{p}K_b + \log ([\text{salt}]/[\text{base}])$  is the Henderson-Hasselbalch
- Example:  $\text{NH}_4\text{OH} / \text{NH}_4\text{Cl}$ ,  $\text{NH}_3 / \text{NH}_4\text{Cl}$ ,  $\text{NH}_3 / (\text{NH}_4)_2\text{CO}_3$
- **Buffer Capacity:** The number of millimoles of acid or base to be added to a litre of buffer solution to change the pH by one unit is the Buffer capacity of the buffer.  
Formula: Buffer Capacity = millimoles of acid or base / ( $\Delta\text{pH}$ )

**Solubility:**

- The solubility of a substance is the amount of that substance that will dissolve in a given amount of solvent. "Solubility" may be considered to be equilibrium; the equilibrium is

between solid and ions in solution. Any ionic solid is 100% ionized in aqueous solution; once it actually dissolves.

### **Factors Affecting Solubility:**

- Temperature: Solubility generally increases with temperature.
- Common ion effect: Common ions reduce solubility
- pH of solution: pH affects the solubility of ionic compounds.
- Formation of complex ion: The formation of complex ion increases solubility
- Some salts are soluble but most are insoluble or slightly soluble in water.
- A saturated solution is a solution that contains the maximum amount of solute that can dissolve in a solvent.
- The solubility of a salt is the amount of solid that dissolved in a known volume of saturated solution.
- The unit of solubility used may be  $\text{g L}^{-1}$  or  $\text{mol L}^{-1}$
- **Molar solubility** is the maximum number of moles of solute that dissolves in a certain quantity of solvent at a specific temperature.

### **Different types of solution**

- Unsaturated solution: More solute can be dissolved in it.
- Saturated solution: No more solute can be dissolved in it. Any more of solute you add will not dissolve. It will precipitate out.
- Super saturated solution: Has more solute than can be dissolved in it. The solute precipitates out.

### **Solubility product constant.**

- $K_{sp}$  is the product of the molar concentrations of the ions involved in the equilibrium, each raised to the power of its stoichiometric coefficient in the equilibrium equation.
- $K_{sp}$  is called the solubility product constant.
- The degree of solubility of a salt is shown by the value of  $K_{sp}$ .
- Soluble salt such  $\text{NaCl}$  and  $\text{KNO}_3$  has an extremely high value of  $K_{sp}$ .
- The smaller the value of  $K_{sp}$  the less soluble the compound in water.
- Temperature  $\uparrow$ , solubility  $\uparrow$ ,  $K_{sp}$   $\uparrow$
- **$K_{sp} = x^x y^y (S)^{x+y}$** 
  - $X = \text{No of cation} = 1$ ,  $y = \text{No of Anion} = 2$ ,  $S$  is solubility of salt
- If we mix a solution containing  $M^+$  ions with one containing  $A^-$  ions, the ionic product,  $Q_{sp}$  is given by :  $Q_{sp} = [M^+] [A^-]$
- $Q_{sp} < K_{sp}$ ; Solution is not saturated. Solid will dissolve and no precipitate formed.
- $Q_{sp} = K_{sp}$ ; Saturated solution formed. System is in equilibrium.
- $Q_{sp} > K_{sp}$ ; Solution is supersaturated; Ions will form precipitate until the ionic concentration product of the system equals the  $K_{sp}$  (until the system reaches equilibrium).
